Introduction

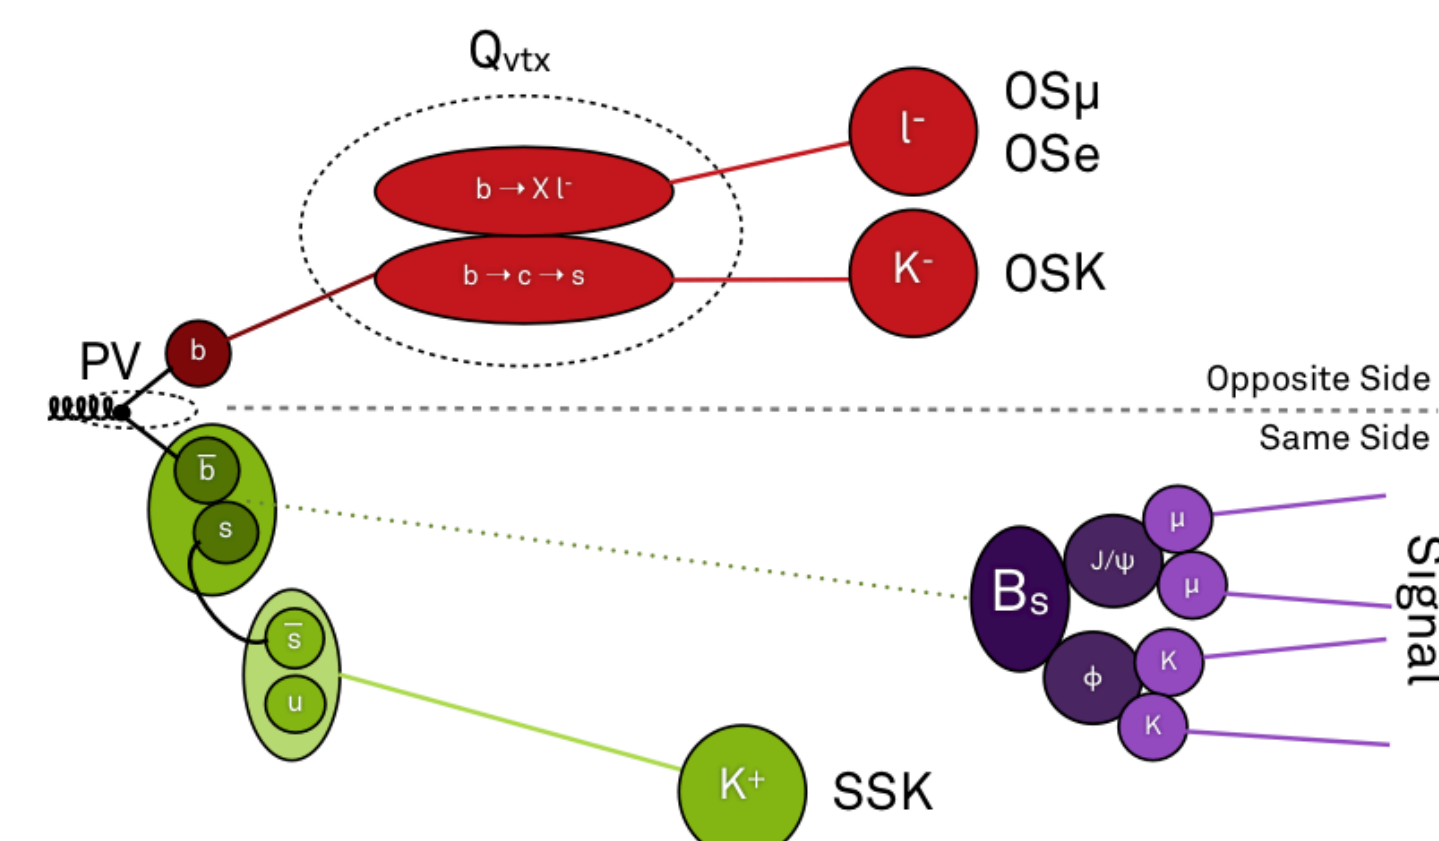

The identification of the flavour of reconstructed B^0 and B_s mesons at production is crucial for the measurements of oscillations and time-dependent CP asymmetries.

This process is known as **Flavour Tagging** (FT).

Flavour Tagging

Two independent algorithms provide informations to tag the initial flavour of the B candidate

- **Same side tagger** (SS) from the fragmentation of the b quark producing the signal B -meson a correlated particle is produced
 - Pion, for B_u/d ($SS\pi$)
 - Kaon, for B_s (SSK)
- **Opposite side tagger** (OS) The non-signal b quark of the $b\bar{b}$ -pair is exploited
 - overall charge of the secondary vertex (Q_{vtx})
 - lepton from semi-leptonic B decays ($OS\mu$ and OSe)
 - kaon from the $b \rightarrow c \rightarrow s$ decay chain (OSK)

Performance of tagging algorithms:

- **mistag**: fraction of events with a wrong tagging decision

$$\omega = \frac{W}{R + W}$$

- **tagging efficiency**: fraction of events with a tagging decision

$$\epsilon_{tag} = \frac{R + W}{R + W + U}$$

- **tagging power**: effective tagging efficiency indicates the statistical precision of the sample

$$\epsilon_{eff} = \epsilon_{tag}(1 - 2\omega)^2$$

where R, W, U are the number of correctly tagged, incorrectly tagged, and untagged events. The tagging algorithms were developed and studied using simulated events [1].

Control channels

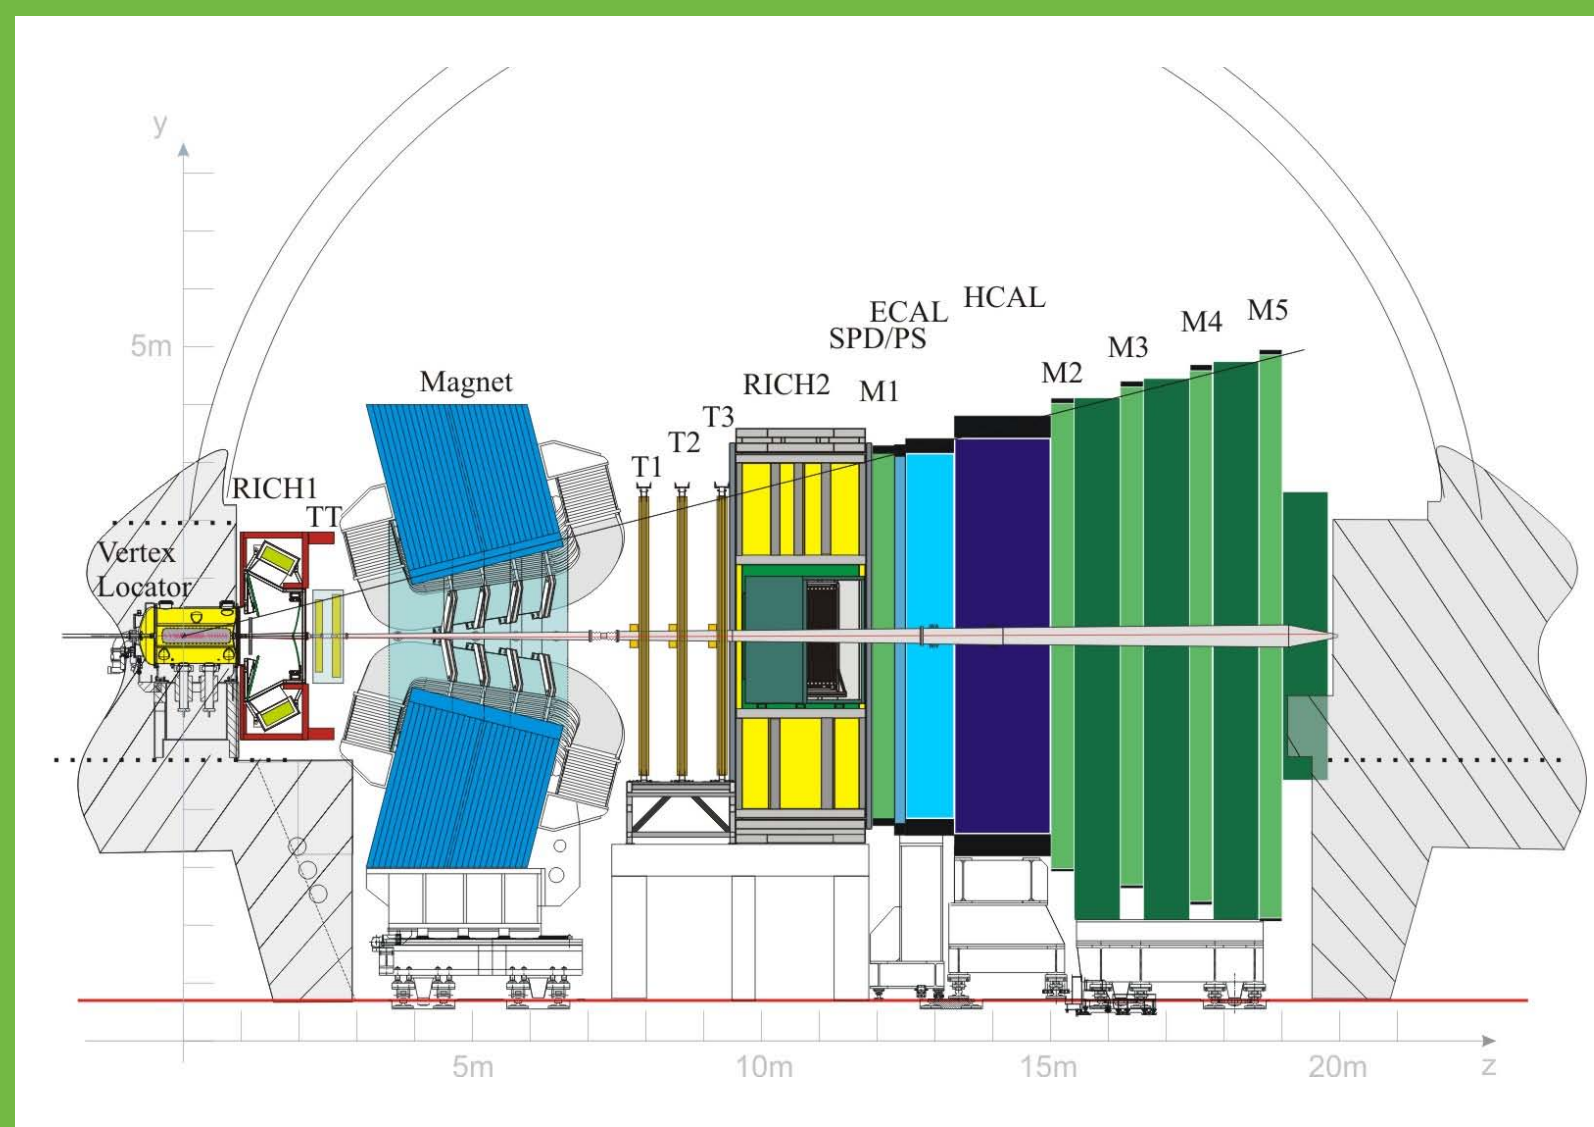

The mistag probability can be measured in data using flavour-specific decay channels, e.g.:

- $B^+ \rightarrow J/\psi K^+$
- $B^0 \rightarrow J/\psi K^{*0}$
- $B^0 \rightarrow D^{*-} \mu^+ \nu_\mu$

In a charged channel, it is possible to compare the tag decision with the charge of the signal to determine if the decision is wrong.

In a neutral channel, the mistag probability can be extracted from the time-dependent mixing asymmetry

$$\mathcal{A}_{mix}(t) = (1 - 2\omega) \cos(\Delta m_d t)$$

Calibration of mistag probabilities

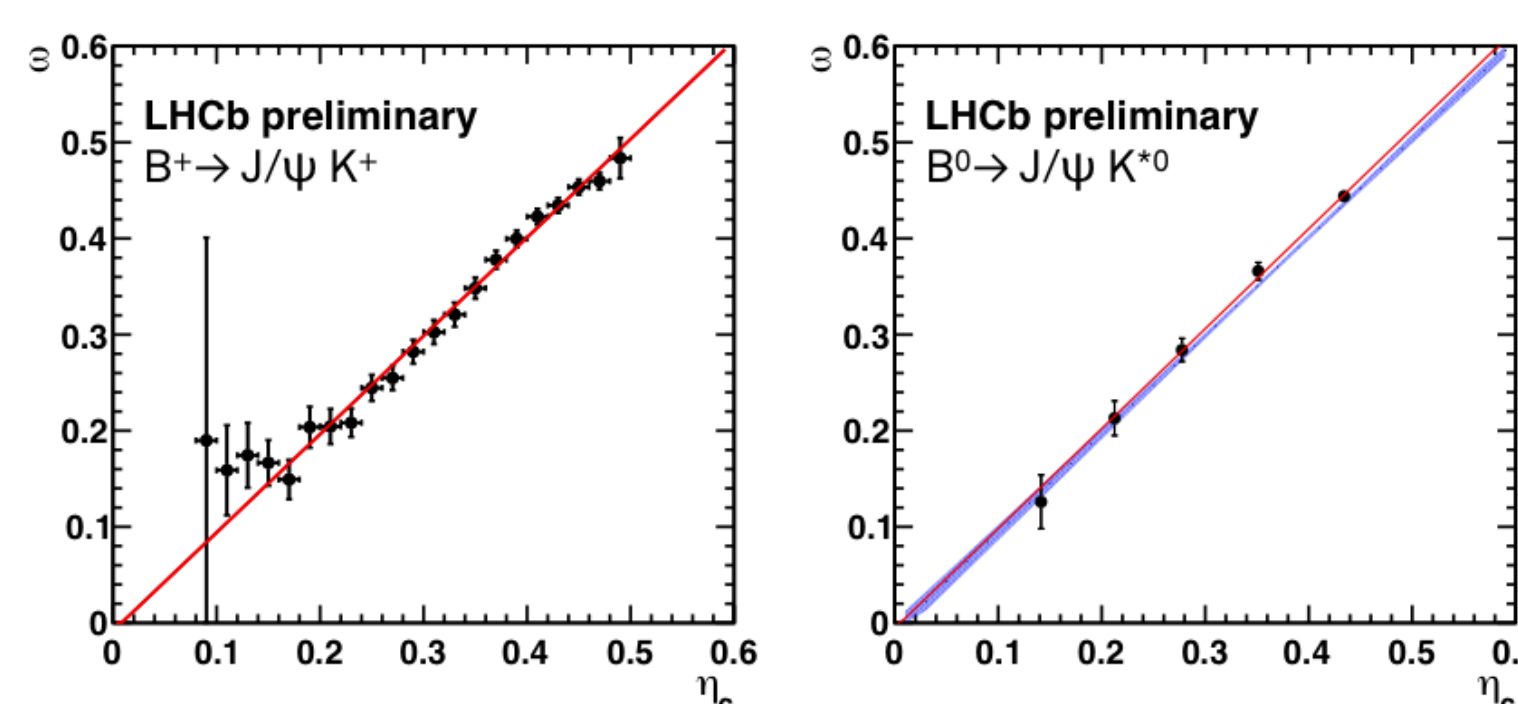

For each tagger, the per event probability η of the tag decision to be wrong is estimated by a neural net (NN) using properties of the tagger and the event itself.

To calibrate the neural net output, the true mistag ω is extracted from the self-tagged control channel $B^+ \rightarrow J/\psi K^+$. A linear dependence $\omega(\eta)$ is assumed to calibrate the predicted mistag probability:

$$\omega(\eta) = p_0 + p_1 (\eta - \langle \eta \rangle)$$

where p_0 and p_1 are free parameters, and $\langle \eta \rangle$ is the mean calculated mistag. Afterwards, the calibration can be validated using another control channel.

The calibration results [5] for 1 fb⁻¹ of data recorded in 2011 are:

In the right plot the calibration obtained from the $B^+ \rightarrow J/\psi K^+$ sample is superimposed as the blue area. [5]

	p_0	p_1	$\langle \eta \rangle$
$B^+ \rightarrow J/\psi K^+$	0.392 ± 0.002	1.035 ± 0.021	0.391

all uncertainties are statistical only

The calibration is consistent among the different channels. The main systematic uncertainties are:

- **Run period**
Split the data sample according to run periods and to the magnet polarity; check for detector asymmetries
- **Signal B flavour**
Due to possibly different particle/anti-particle interactions, the data sample is split according to the signal flavour
- **Fit model assumptions**
Different distributions of the mistag probability in the fit model are investigated
- **Distribution of mistag in different channels**
Different distributions of the mistag probability among the control channels as well as the p_T distributions and the dependence of the mean mistag on this p_T are studied

The largest systematic uncertainty originates from the dependence on the signal flavour.

	δp_0	δp_1
Total	± 0.005	± 0.012

Opposite side tagging performance

The OS tagging performance can be computed on different ways:

- Dividing the sample in bins of η_c , where η_c is the calibrated mistag. Then fit for each sub-sample to estimate the tagging power. Since the sub-samples are disjoint, the OS tagging power is the sum of the single bins.
- Using the event-by-event mistag by summing the mistag on all signal events.

For the three control channels the performances for 0.37 fb⁻¹ of data recorded in the first half of 2011 are:

$$B^+ \rightarrow J/\psi K^+$$

Taggers	ϵ_{tag} [%]	ω [%]	$\epsilon_{tag}(1 - 2\omega)^2$ [%]
μ	4.8 ± 0.1	29.9 ± 0.7	0.77 ± 0.07
e	2.2 ± 0.1	33.2 ± 1.1	0.25 ± 0.04
K	11.6 ± 0.1	38.3 ± 0.5	0.63 ± 0.06
Q_{vtx}	15.1 ± 0.1	40.0 ± 0.4	0.60 ± 0.06
OS sum of η_c bins	27.3 ± 0.2	36.2 ± 0.5	2.07 ± 0.11
OS event-by-event	27.3 ± 0.1	36.1 ± 0.3	2.10 ± 0.08

$$B^0 \rightarrow J/\psi K^{*0}$$

Taggers	ϵ_{tag} [%]	ω [%]	$\epsilon_{tag}(1 - 2\omega)^2$ [%]
μ	4.8 ± 0.1	34.3 ± 1.9	0.48 ± 0.12
e	2.2 ± 0.1	32.4 ± 2.8	0.27 ± 0.10
K	11.4 ± 0.2	39.6 ± 1.2	0.49 ± 0.13
Q_{vtx}	14.9 ± 0.2	41.7 ± 1.1	0.41 ± 0.11
OS sum of η_c bins	27.1 ± 0.3	38.0 ± 0.9	1.57 ± 0.22
OS event-by-event	27.3 ± 0.3	36.2 ± 0.3	2.09 ± 0.09

$$B^0 \rightarrow D^{*-} \mu^+ \nu_\mu$$

Taggers	ϵ_{tag} [%]	ω [%]	$\epsilon_{tag}(1 - 2\omega)^2$ [%]
μ	6.08 ± 0.04	33.3 ± 0.4	0.68 ± 0.04
e	2.49 ± 0.02	34.3 ± 0.7	0.25 ± 0.02
K	13.36 ± 0.05	38.3 ± 0.3	0.74 ± 0.04
Q_{vtx}	16.53 ± 0.06	41.5 ± 0.3	0.48 ± 0.03
OS sum of η_c bins	30.48 ± 0.08	37.0 ± 0.3	2.06 ± 0.06
OS event-by-event	30.1 ± 0.1	35.5 ± 0.3	2.53 ± 0.10

all uncertainties are statistical only

The differences in the efficiencies are mainly due to different p_T spectra. Moreover, different trigger requirements can effect ϵ_{tag} and ω .

Conclusion

The optimisation and calibration of the flavour tagging is performed on the first 0.37 fb⁻¹ collected in 2011. By using the calibrated OS taggers the tagging power was $\epsilon_{tag}(1 - 2\omega)^2$ finally determined on an event-by-event basis to be:

- **(2.10 ± 0.08 ± 0.24)%** in $B^+ \rightarrow J/\psi K^+$
- **(2.09 ± 0.09 ± 0.24)%** in $B^0 \rightarrow J/\psi K^{*0}$
- **(2.53 ± 0.10 ± 0.27)%** in $B^0 \rightarrow D^{*-} \mu^+ \nu_\mu$

On the full dataset of 2011 of 1 fb⁻¹ the tagging power is:

- **(2.29 ± 0.07 ± 0.26)%**

for the channel $B_s \rightarrow J/\psi \phi$, and

- **2.1%**

for the channel $B_s \rightarrow J/\psi f_0(980)$, which are both used for measurements of the CP violating phase ϕ_s [3,5].

Moreover, some other time dependent measurements in the CP field have already be done using this flavour tagging [4,6].

(first uncertainty is statistical, the second is systematic)
